

# Multivariable regression

Regression

Brian Caffo, Jeff Leek, Roger Peng Johns Hopkins Bloomberg School of Public Health

### Consider the following simulated data

Code for the first plot, rest omitted (See the git repo for the rest of the code.)

```
n <- 100; t <- rep(c(0, 1), c(n/2, n/2)); x <- c(runif(n/2), runif(n/2));
beta0 <- 0; beta1 <- 2; tau <- 1; sigma <- .2
y <- beta0 + x * beta1 + t * tau + rnorm(n, sd = sigma)
plot(x, y, type = "n", frame = FALSE)
abline(lm(y ~ x), lwd = 2)
abline(h = mean(y[1 : (n/2)]), lwd = 3)
abline(h = mean(y[(n/2 + 1) : n]), lwd = 3)
fit <- lm(y ~ x + t)
abline(coef(fit)[1], coef(fit)[2], lwd = 3)
abline(coef(fit)[1] + coef(fit)[3], coef(fit)[2], lwd = 3)
points(x[1 : (n/2)], y[1 : (n/2)], pch = 21, col = "black", bg = "lightblue", cex = 2)
points(x[(n/2 + 1) : n], y[(n/2 + 1) : n], pch = 21, col = "black", bg = "salmon", cex = 2)</pre>
```

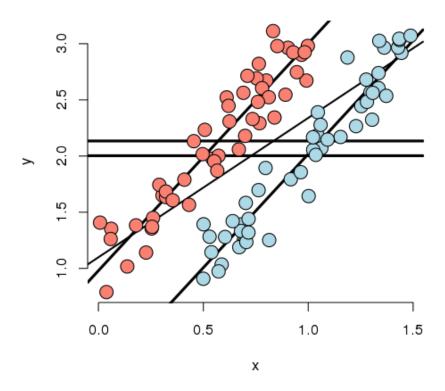

- · The X variable is unrelated to group status
- · The X variable is related to Y, but the intercept depends on group status.
- · The group variable is related to Y.
  - The relationship between group status and Y is constant depending on X.
  - The relationship between group and Y disregarding X is about the same as holding X constant

- · The X variable is highly related to group status
- The X variable is related to Y, the intercept doesn't depend on the group variable.
  - The X variable remains related to Y holding group status constant
- · The group variable is marginally related to Y disregarding X.
- · The model would estimate no adjusted effect due to group.
  - There isn't any data to inform the relationship between group and Y.
  - This conclusion is entirely based on the model.

- · Marginal association has red group higher than blue.
- · Adjusted relationship has blue group higher than red.
- · Group status related to X.
- · There is some direct evidence for comparing red and blue holding X fixed.

- $\cdot$  No marginal association between group status and Y.
- · Strong adjusted relationship.
- · Group status not related to X.
- · There is lots of direct evidence for comparing red and blue holding X fixed.

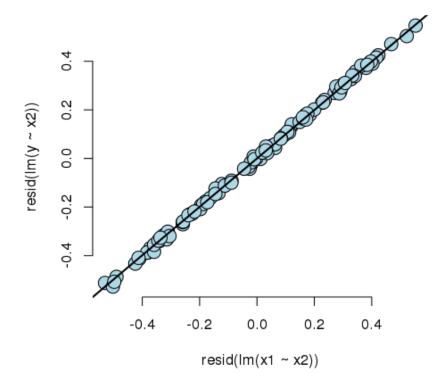

- · There is no such thing as a group effect here.
  - The impact of group reverses itself depending on X.
  - Both intercept and slope depends on group.
- · Group status and X unrelated.
  - There's lots of information about group effects holding X fixed.

#### Do this to investigate the bivariate relationship

```
library(rgl)
plot3d(x1, x2, y)
```

#### Residual relationship

- · X1 unrelated to X2
- · X2 strongly related to Y
- · Adjusted relationship between X1 and Y largely unchanged by considering X2.
  - Almost no residual variability after accounting for X2.

### Some final thoughts

- · Modeling multivariate relationships is difficult.
- · Play around with simulations to see how the inclusion or exclustion of another variable can change analyses.
- · The results of these analyses deal with the impact of variables on associations.
  - Ascertaining mechanisms or cause are difficult subjects to be added on top of difficulty in understanding multivariate associations.
